$$\Psi = \Psi(\mathbf{r}_1, \mathbf{r}_2, \mathbf{r}_3, \dots, \mathbf{r}_n)$$

Methane

N₂

Ethanol

Solved by approximations in computational chemistry?

Commercial databases

- 164 million molecules
- 15k added daily

Scale

- One person: 1 million compounds/second
- 10 billion people on earth
- 10^{26} universe ages to go through

Face centered cubic and 70 elements only

9 primitive cells

- Binary 10^7
- Ternary: 10^{13}
- Quaternary: 10^{15}

27 primitive cells

- Binary: $\sim 10^{17}$
- Ternary: $\sim 10^{29}$
- Quaternary: $\sim 10^{36}$

Speed does not matter:
even enumeration is impossible.

Idea

Treat system changes perturbatively^[1,2]

Build a Taylor/Padé approximant^[3]: often 100.000 times faster

Steps

Choose system

Alter system, calculate property response functions

Predict many modified systems

Few highly accurate calculations
instead of many intermediate ones

$$\hat{H} = \hat{H}(\underbrace{Z_i}_{4N}, \underbrace{\mathbf{R}_i}_{1D, \text{ close to } \sum_i Z_i}, \underbrace{N_e}_{1D}, \sigma)$$

Joseph Wright, 1771

Without Perturbation

With Perturbation

Systems

- Any
- Known
- Approximated

Differentiable / Analytic + Converge quickly

- ✓ Total Energy ^[1,2]
- ✓ Dipole moments ^[2]
- ✓ Deprotonation energies ^[3]
- ✓ Photoelectron circular dichroism ^[5]
- ✓ Electron density ^[1,2]
- ✓ Non-covalent interactions ^[1]
- ✓ Ionisation Energy ^[4]
- ✓ Orbital eigenvalues ^[2]
- ✓ Binding energies ^[1,2]
- ✓ Electron Affinity ^[4]

In progress

NMR spectra, QMC energies

Tested in: Gaussian, Psi4, PySCF, ORCA, MRCC, cp2k, CPMD

Tested with: HF, KS-DFT, CCSD

1 | GFvR, O. A. von Lilienfeld, *Phys. Rev. Res.*, 2020. **2** | GFvR, *J. Chem. Phys.*, 2021. **3** | GFvR, O. A. von Lilienfeld, *Phys. Chem. Chem. Phys.*, 2020. **4** | E Eikey, A Maldonado, C Griego, GFvR, J Keith, *J. Chem. Phys.*, 2022. **5** | GFvR, A Artemyev, B Lagutin, P Demekhin, *J. Chem. Phys.*, 2024.

Interpolate between molecular isoelectronic Hamiltonians

$$\hat{H}(\lambda) \equiv \lambda \hat{H}_t + (1 - \lambda) \hat{H}_r$$

Taylor expansion around reference molecule

$$E_t = E_r + \Delta E^{\text{NN}} + \int_{\Omega} d\mathbf{r} \sum_{n=0}^{\infty} \frac{1}{(n+1)!} \Delta v \frac{\partial^n \rho_{\lambda}(\mathbf{r})}{\partial \lambda^n} \Big|_{\lambda=0}$$

- Gives consistent energies, densities, forces, ...
- Uses the same derivatives for all predictions

AT THIS POINT, YOU'RE PROBABLY THINKING, "I LOVE THIS EQUATION AND WISH IT WOULD NEVER END!"
WELL, GOOD NEWS!

Taylor expansion

- First terms accurate enough
 - Truncate early
- Converges to the right value
- Large convergence radius
- Scales with chemical space

Taylor expansion

- Large changes still converge (more slowly)
- Geometric response can be recovered

Scaling with chemical space

- 1 derivative for second order
- 5 derivatives for third order

C_{20}

$3.1 \cdot 10^6$
targets

QA: 80.000x faster

BN-doped coronene dimer

- Identify most/least attractive doping pattern
- Design case

QA: 20.000x faster

$2.8 \cdot 10^{10}$ targets

Fundamentally new symmetry

Electronic energy only

Bond energy rules

Consecutive Elements

Q R S

B C N

$$E_{QR} \simeq E_{SR} + 0.5(E_{QQ} - E_{SS})$$

Speed up machine learning

x 414 M

QA: Millions at once!

Design rules in order of decreasing strength

- Add BN pairs
- Maximize CC bonds
- Substitute sites shared between rings
- Maximize BN bonds
- Avoid N substitutions on rings sharing a larger amount of bonds with other rings
- Balance BN substitutions in each ring

Not a single QM calculation required!

Angular emission

- Expensive to calculate
- Highly coupled degrees of freedom: multidimensional expansion

$$\frac{d\sigma^\pm}{d\Omega} = \frac{\sigma}{4\pi} \left[1 \pm \underbrace{\beta_1 P_1(\cos \theta)}_{\substack{\text{dichroic} \\ \text{parameter}}} - \frac{1}{2} \underbrace{\beta_2 P_2(\cos \theta)}_{\substack{\text{anisotropy} \\ \text{parameter}}} \right]$$

Data

- 85 pairs of β_i
- Center: $Q_{xyz}=2.5$, $R_{xyz} = 3$, photoelectron = 6 eV

$$\beta_i(\mathbf{x}) \simeq \sum_{|\alpha| \leq k} \frac{\partial^{|\alpha|} \beta_i(\mathbf{a})}{\partial x_1^{\alpha_1} \dots \partial x_n^{\alpha_n}} \frac{(\mathbf{x} - \mathbf{a})^\alpha}{\alpha!}$$

Objective

- Modify **all** Q_i, R_i , photoelectron energy
- Find extremal β_1 , predict matching β_2

Results

- max β_1 : 5.6% \rightarrow 25.8%
- Min β_1 : 5.6% \rightarrow -14.7%

Group terms

- Q_i : Q
- R_i : R
- photoelectron energy: E
- Mixed: count groups

$$\frac{\partial \beta_i}{\partial R_x} \quad \frac{\partial^2 \beta_i}{\partial Q_y^2} \quad \frac{\partial^2 \beta_i}{\partial R_x Q_y}$$

∈ R1 ∈ Q2 ∈ R1 Q1

Results

- Converges quickly
- Few third order terms contribute
- Almost no spatial-spatial coupling

Relate to cost

- Expensive terms also irrelevant
- For molecules, subset only
- Allows for efficient stencil design

Estimated speedup

$$\frac{3^N}{N^2 + 12N - 1}$$

Both energy and density derivatives are hard

- Finite differences expensive, numerical instabilities
- Hellmann-Feynman finite order, basis set inaccurate
- Coupled-perturbed finite order, tedious
- Automatic differentiation niche: DiffiQult, quax, dqc, ...

 ferchault/APDFT  ferchault/APHF

Gaussian basis sets not overly cooperative

- Elements are discrete, derivatives are not
- Density converges more slowly with basis set quality than energy: Problem for APDFT and AIT
- Unless complete basis set limit: Pulay terms

 aspuru-guzik-group/DiffiQult

 CCQC/Quax

 diffqc/dqc **Alchemy!**

 fishjojo/pyscfad

Pseudopotentials

- Discrete Elements, parameters not differentiable

Convergence

- Finite radius
- Not all systems are made equally

Efficient | Re-use knowledge, no one-by-one

Symmetries | Reducing (“folding”) search space

Physics-driven | Predictive power

Differentiable Chemistry | Arbitrary derivatives of many properties

Closed-Form | Explainable and shows structure

Fast Design | Can assess whole regions at once
